Analysis of restenosis in saphenous vein coronary grafts. A long-term follow-up study of 131 patients. A long-term follow-up of 131 patients in whom a saphenous vein was the only available graft to the left anterior descending coronary artery has been studied. The most striking finding was the marked incidence of restenosis at the grafted saphenous vein site (27%). This was significantly more frequent than in the native coronary artery (6%) (P less than 0.01) and than in grafts to the right coronary artery (15%) (P less than 0.05). The severity of the luminal narrowing of the grafted saphenous vein correlated with the severity of disease in the patient. The results show that vein grafts to the left anterior descending coronary artery are prone to recurrence of angina at a higher rate than vein grafts to the right coronary artery.
